# **MAXWELL'S SPOT MEASUREMENTS IN CHANGING WHITE LIGHT SPECTRA**

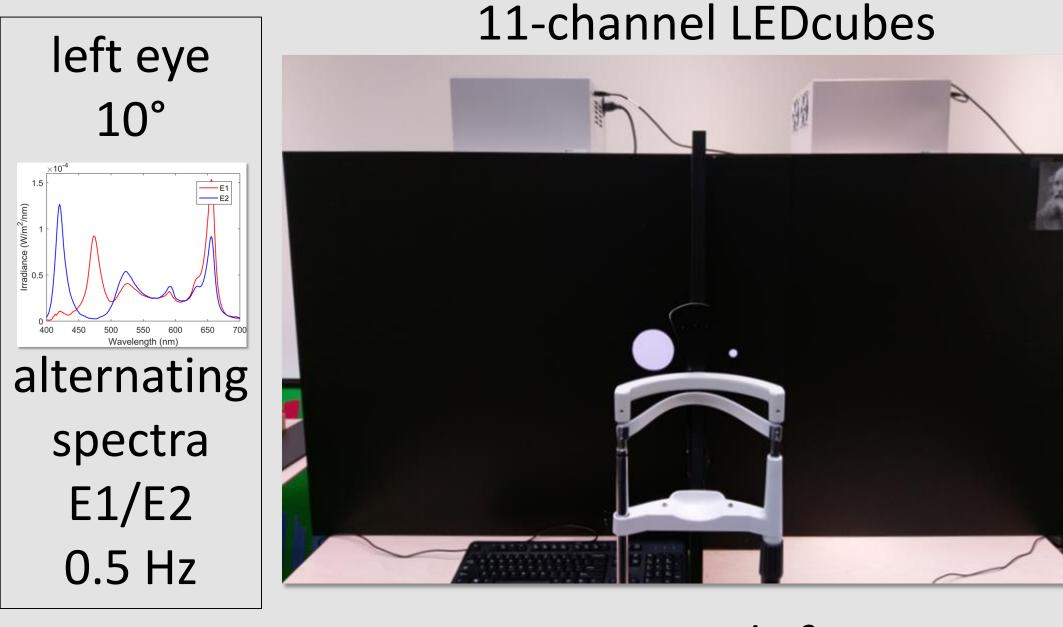

Marcel Lucassen, Tobias Borra, Jan Souman, Luc Schlangen, Philips Lighting Research, Eindhoven, The NETHERLANDS

#### Introduction

- Foveal cones receive less (short-wave) light than peripheral cones due to absorption by macular pigment.
- Normally this goes unnoticed, possibly because of local chromatic adaptation and/or neural filling-in.
- Maxwell's spot is perceived when alternately looking at a blue and a yellow light field. The spot is attributed to the presence of macular pigment.
- Here we show that Maxwell's spot also appears when two white lights are alternated.

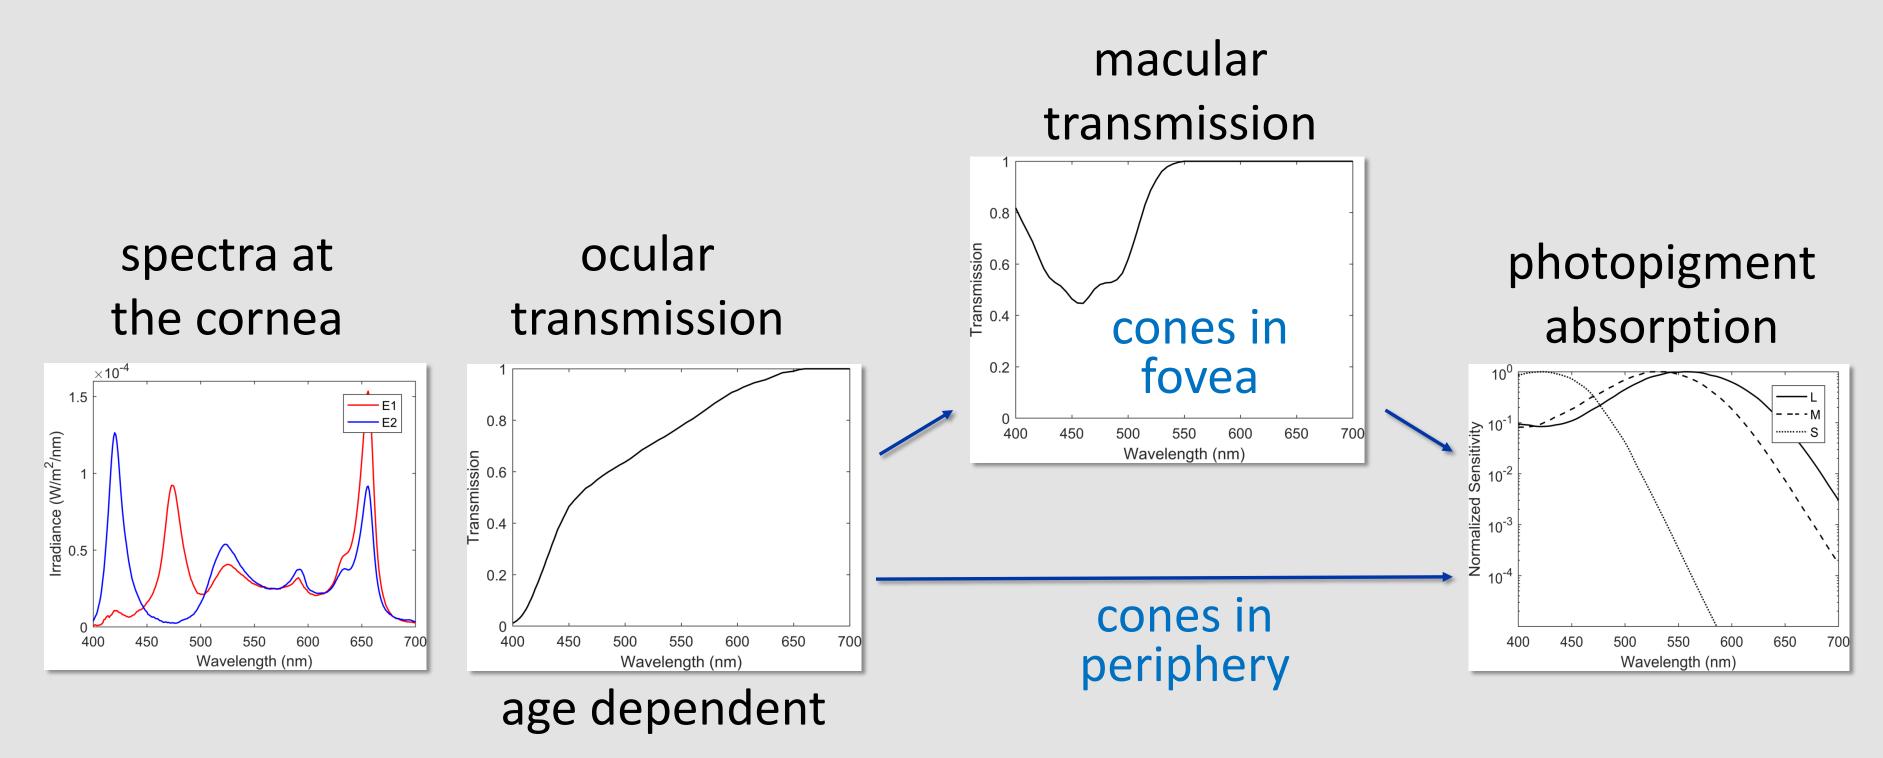

# We matched the appearance of two Maxwell spots, induced by alternating white lights of different spectral composition

### **Successive haploscopic color** matching

 $115 \text{ cd/m}^2$ 

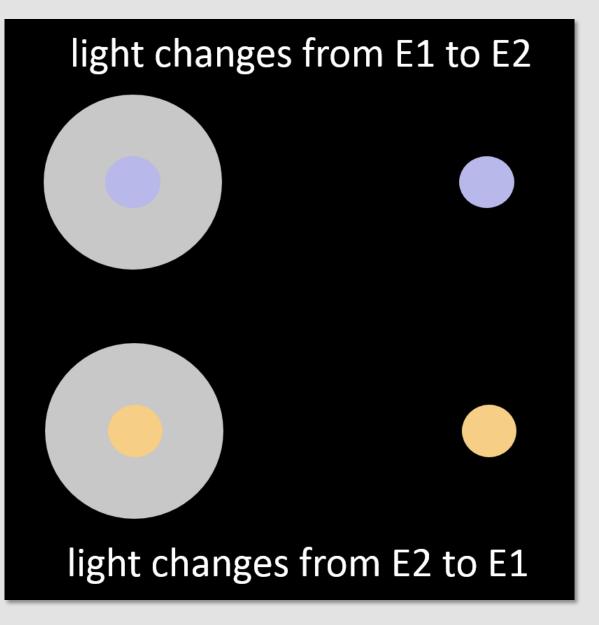

#### From spectra to cone inputs

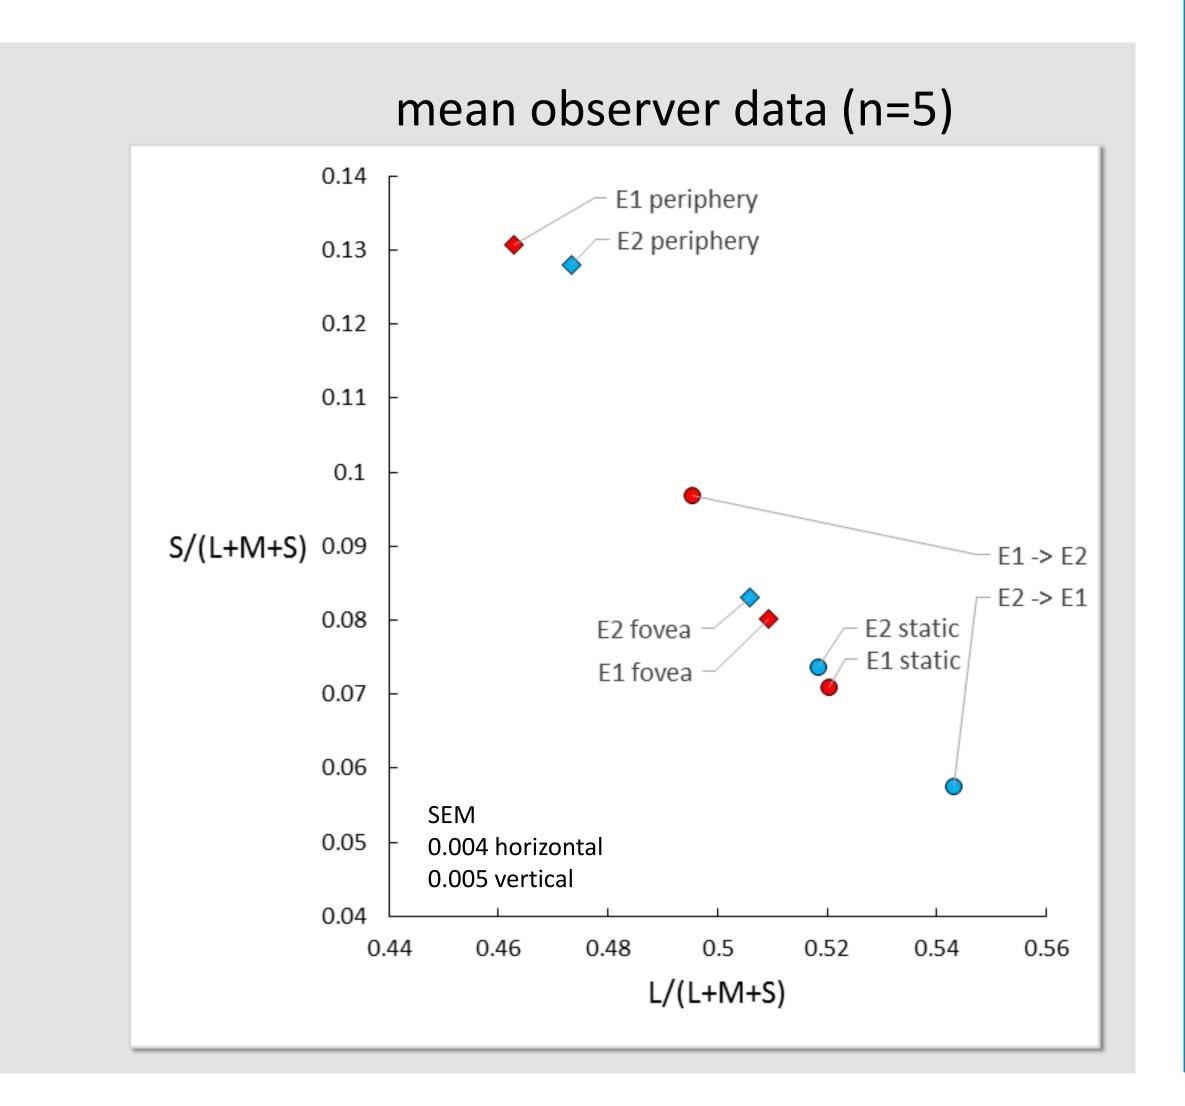

right eye 2°

makes a color match using R,G,B LEDs Maxwell spot appearances

cone input	
ratio	
fovea/peripher	y

cone input

	<b>E1</b>	<b>E2</b>
L	0.91	0.95
Μ	0.83	0.92
S	0.51	0.58

## Main findings

- M's spot can be induced by alternating white lights with different spectral composition
- Sensitivity adjustments of foveal cones alone cannot explain the color of Maxwell's spot
- Additional interaction between peripheral and foveal cones needed to describe our data

## PHILPS
